

How do trees know when to flower?

Janet Prevéy and Constance Harrington
USFS PNW Research Station
Olympia, WA

Timing of flowering is important.....

- Tree phenology is **fascinating** – it is one of the primary ways plants are adapted to their environment
- Flowering phenology can influence outcrossing rates, and success of seed crops
- With changes in weather from year to year - and changes in climate over longer timescales - we see changes in phenology

Timing of flowering is important.....

- Previous work with other tree species shows that **temperature strongly controls phenology**
- However, we lack information on how temperature and other cues determine the timing of reproductive events in Douglas-fir and western redcedar
- If we can develop models of flowering, we can better predict **when** it will occur in the future.....

Research Questions

- Can we accurately model the date of flowering of **Douglas-fir** and **western redcedar** using environmental data?
- Does the relationship between environmental factors and flowering date differ between **species** or between trees from different regions?

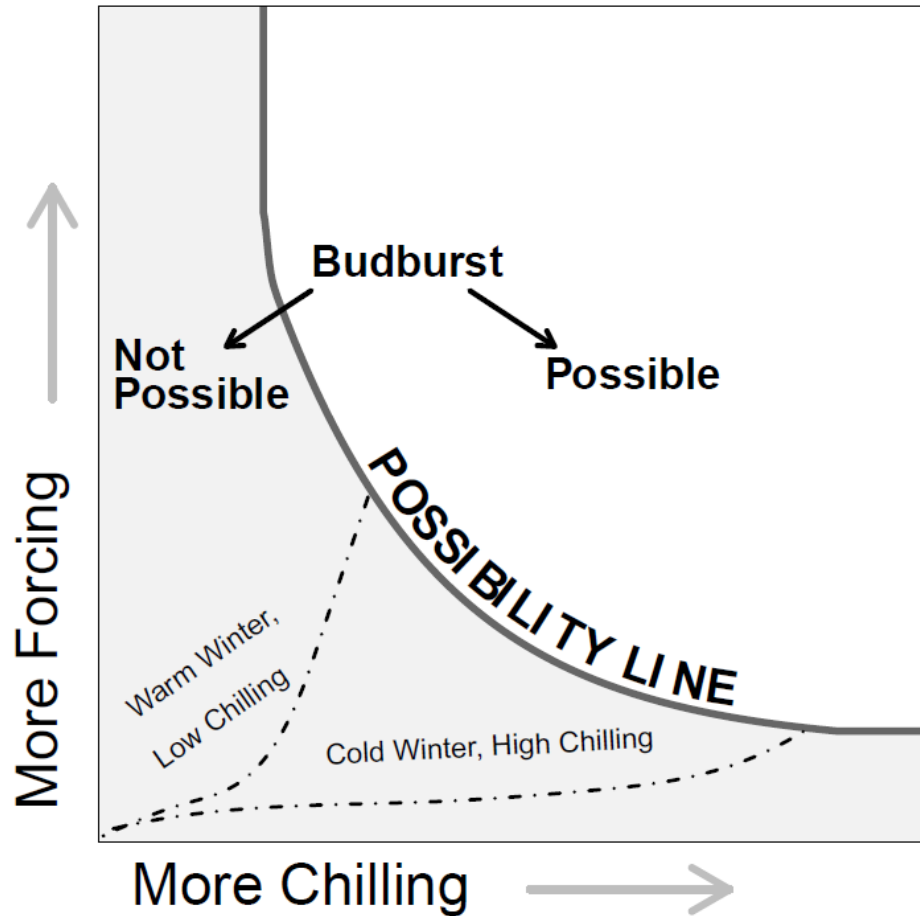

Previous research: **Chilling** and **Forcing** Requirements for vegetative budburst of Douglas-fir

<u>°C</u>	<u>°F</u>
0	32
5	41
10	50
15	59
20	68

Cumulative cold and warm temperatures determine budburst timing and growth initiation of Douglas Fir

(Harrington *et al.* 2010, Ford *et al.* 2016)

Both **chilling** and **forcing** temperatures influence budburst timing – and many combinations can result in budburst

These models allow for predictions of vegetative budburst based on temperature data

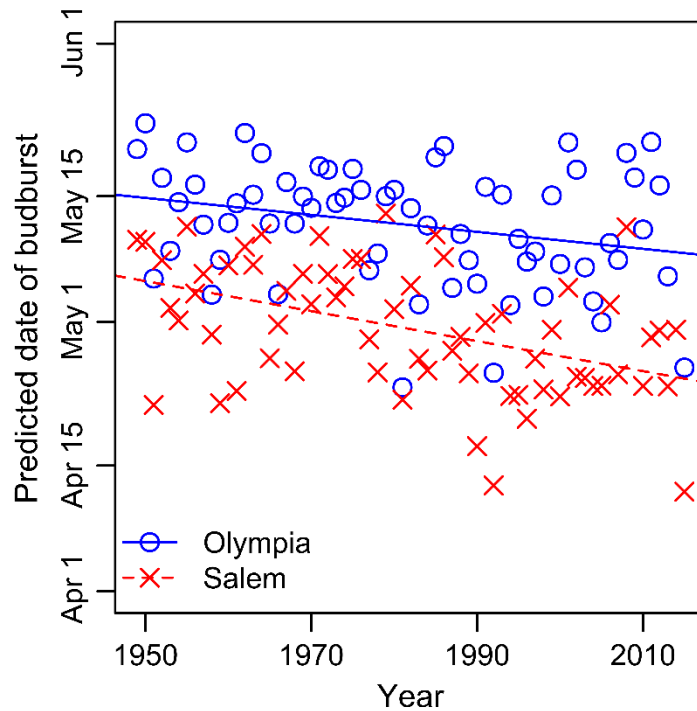

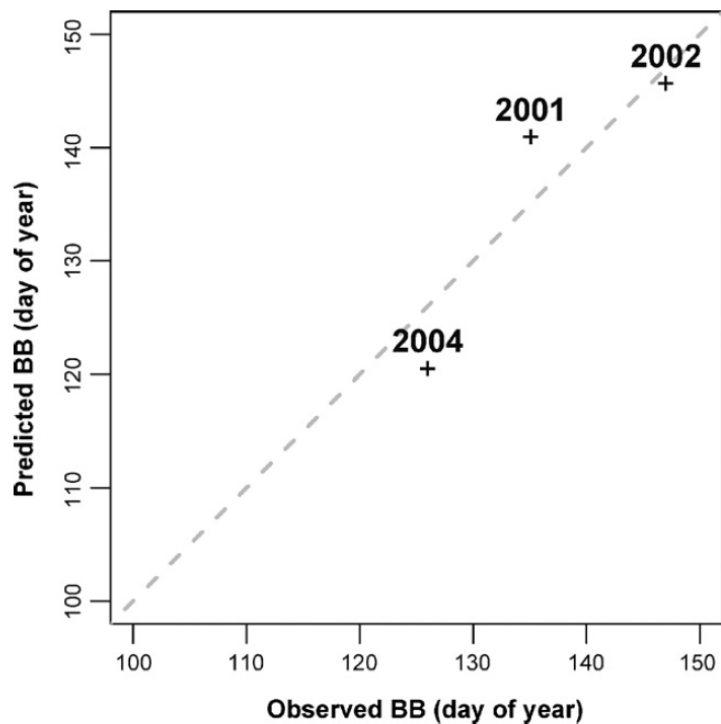

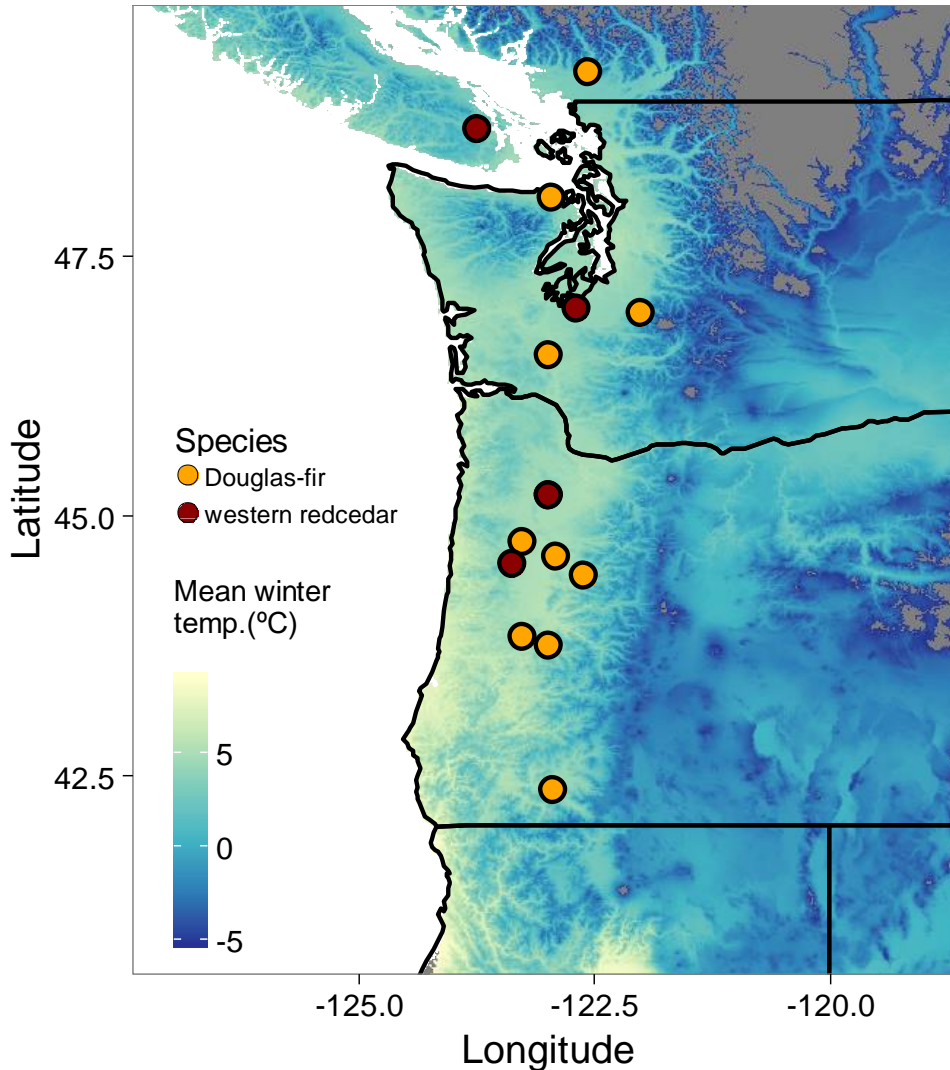

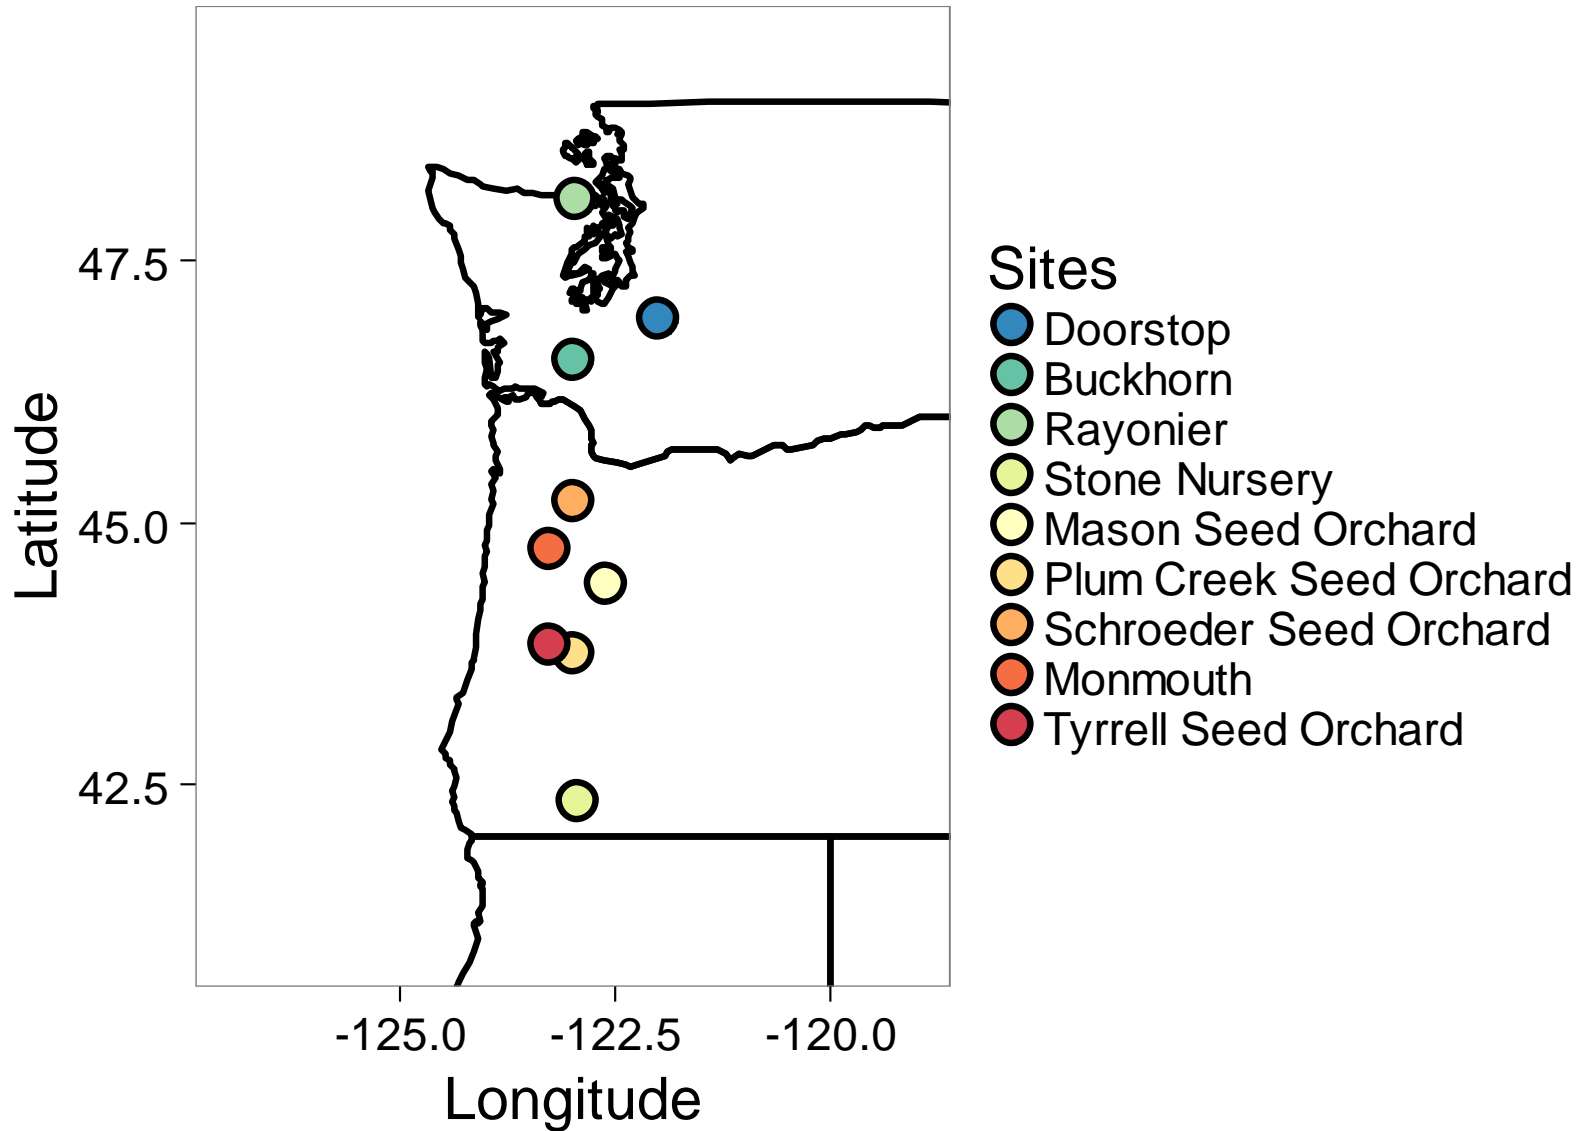

Fig. 8. Application of the possibility-line approach to prediction of date of budburst for 2001, 2002, and 2004 at Fall River, WA. The dotted line shows the 1:1 relationship between observed and predicted dates.

Current locations with reproductive phenology data

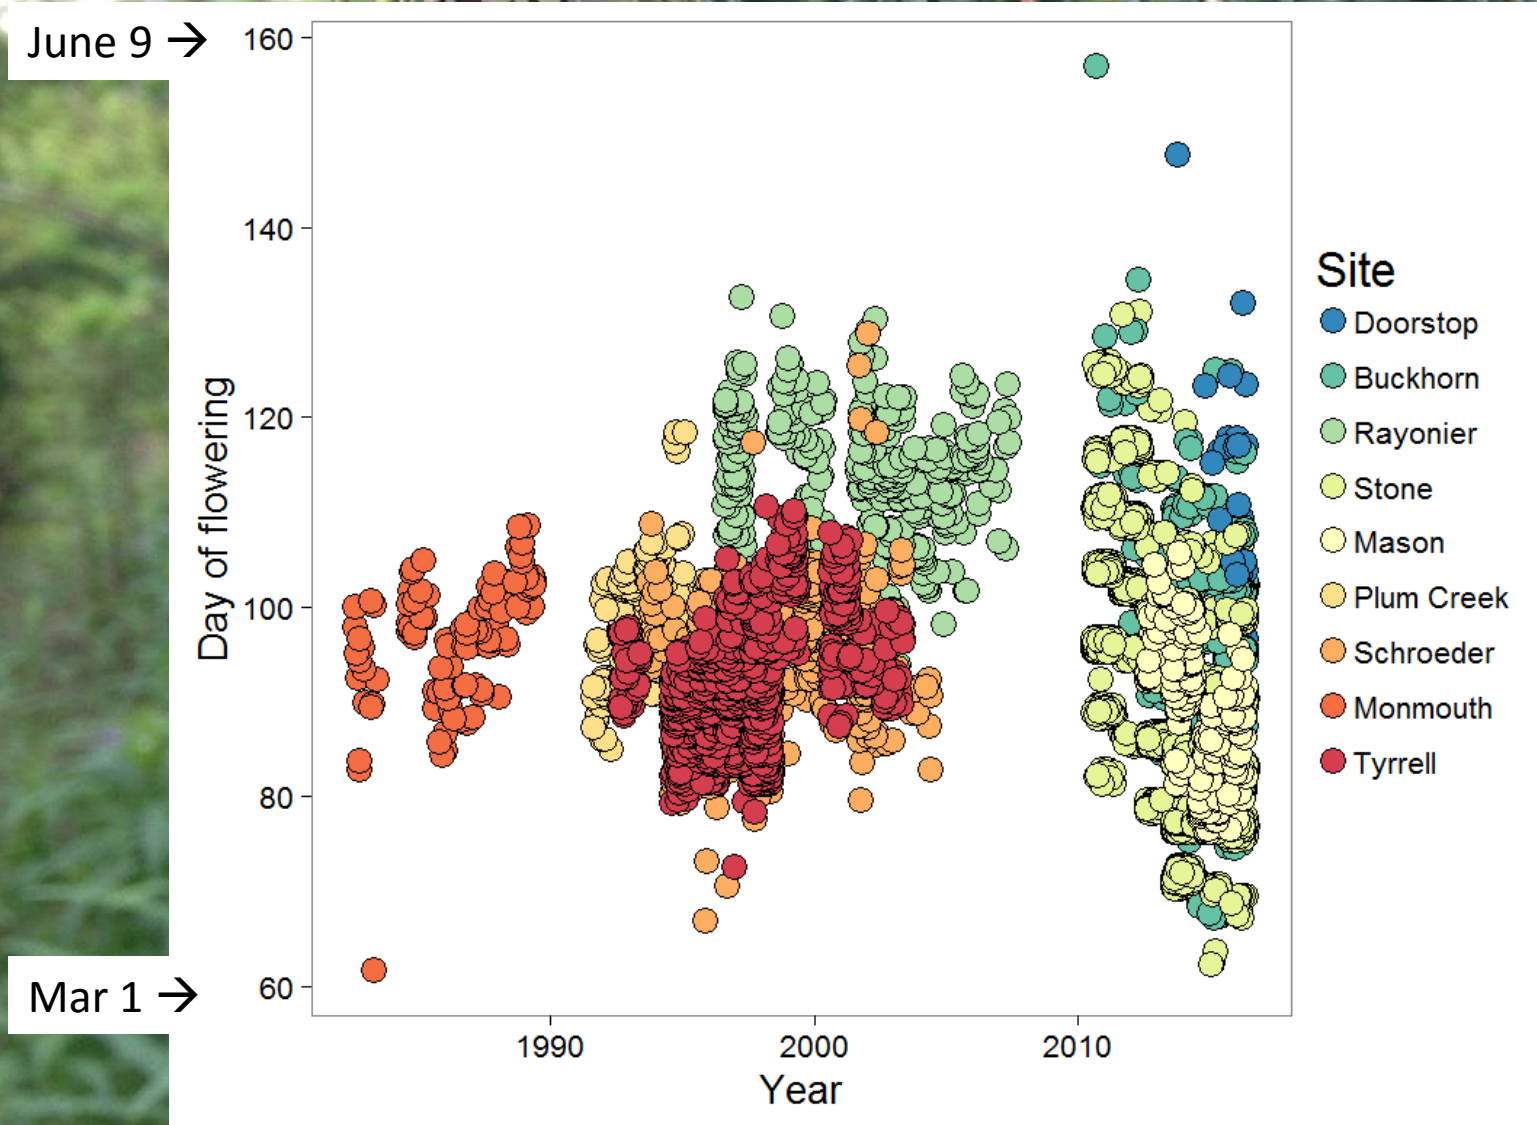

- Crossing or flowering dates from trees at 14 sites
- 1-10 years of data per site
- 9 locations from operational seed orchards

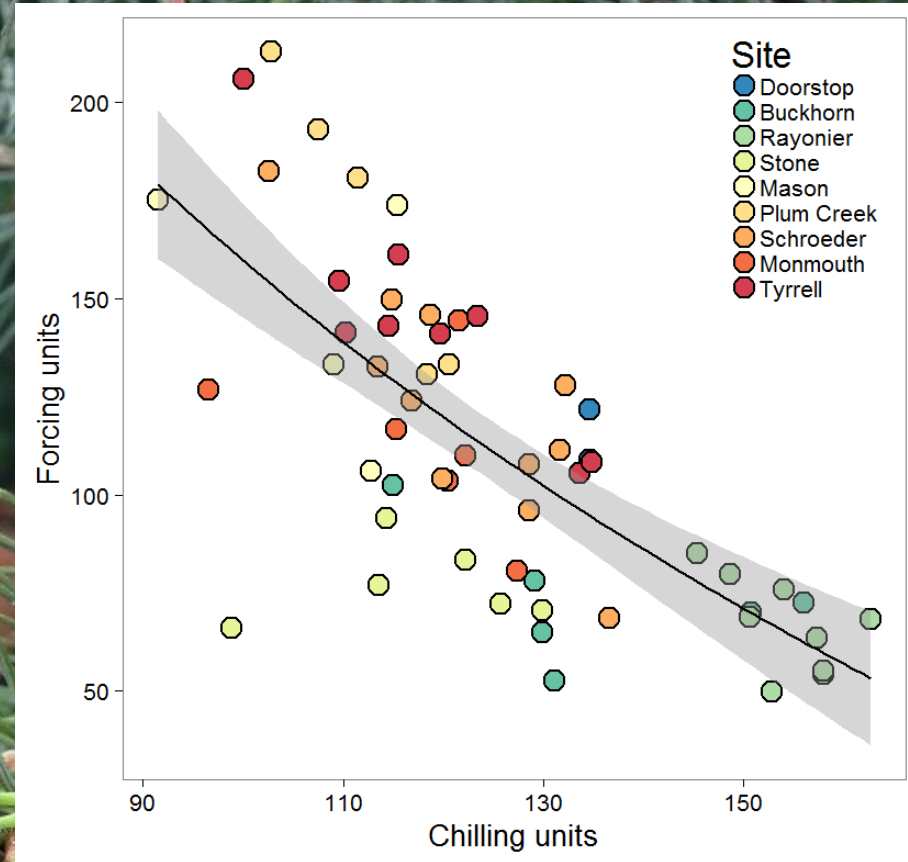

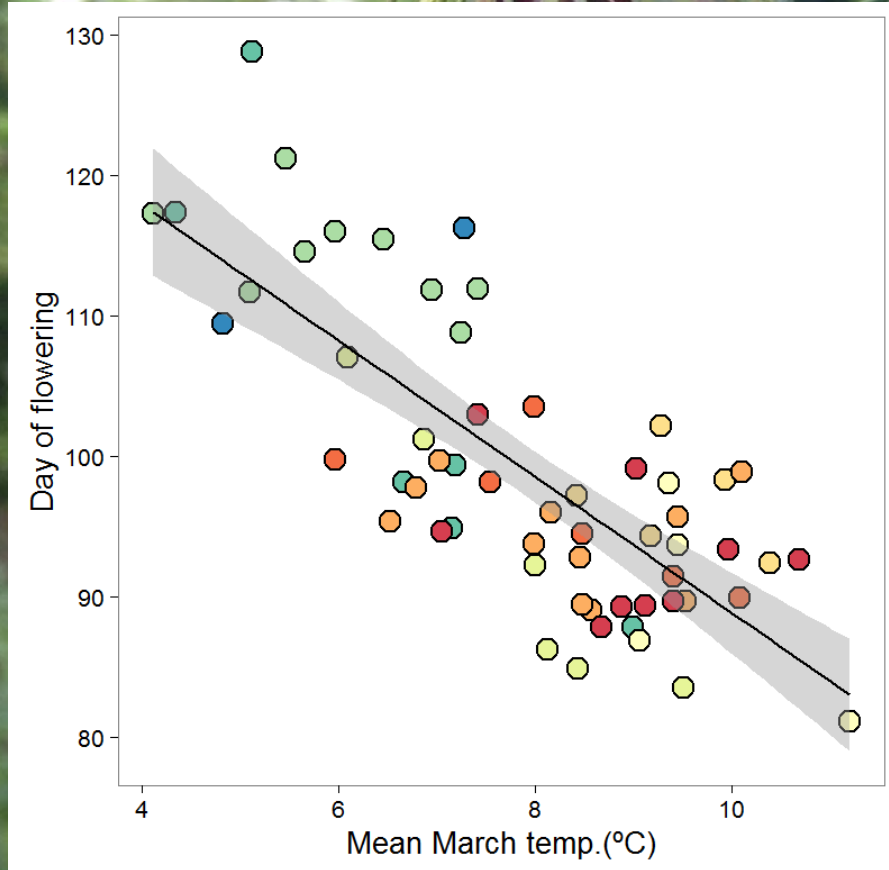

Preliminary Results – Douglas-fir

Preliminary Results – Douglas-fir

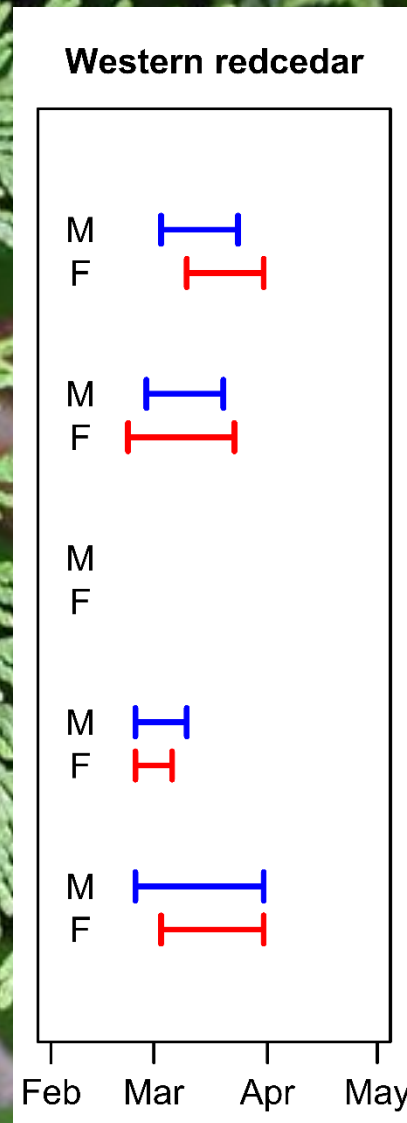

Preliminary Results – Douglas-fir

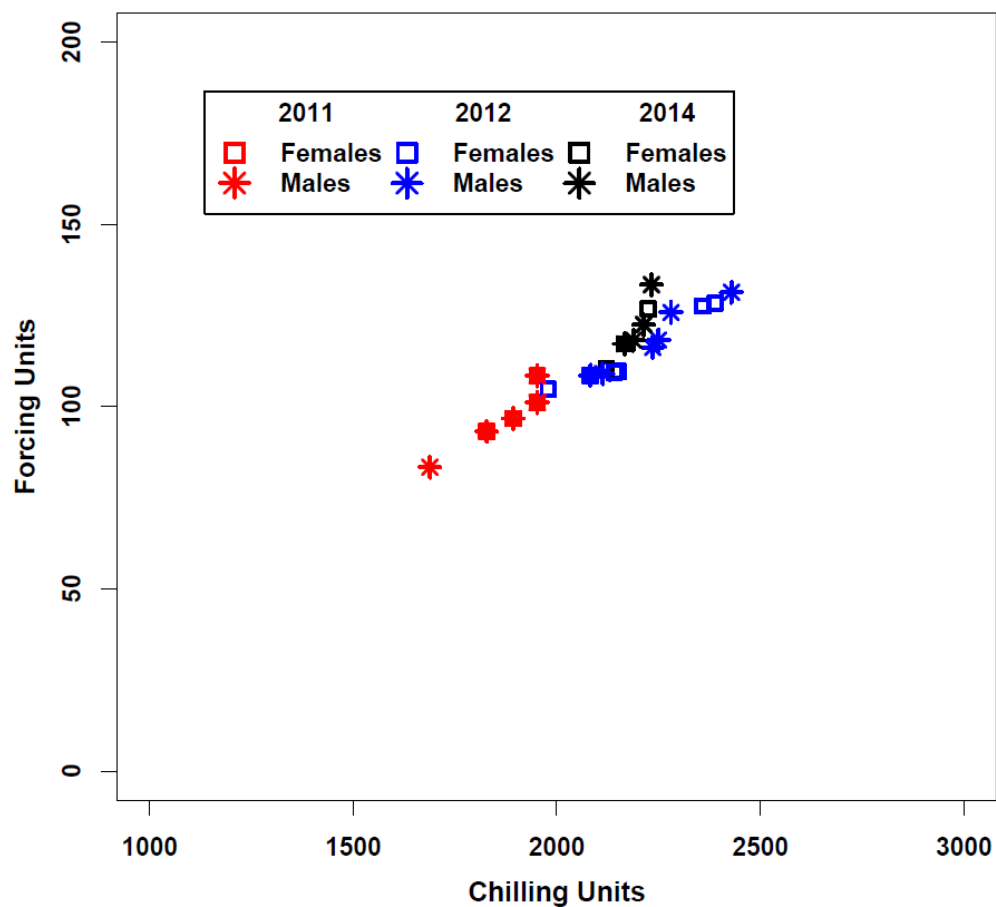

Preliminary evidence that both chilling and forcing temperatures help determine date of flowering of Douglas-fir.....

Preliminary Results – western redcedar

Preliminary Results – western redcedar

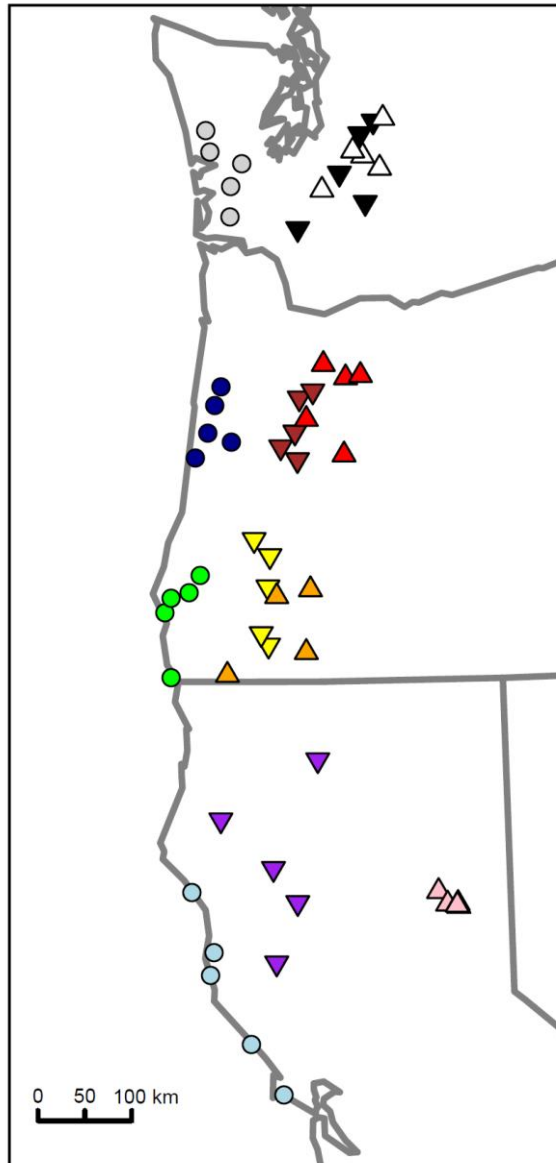

Chilling temperatures may not be as important for redcedar?

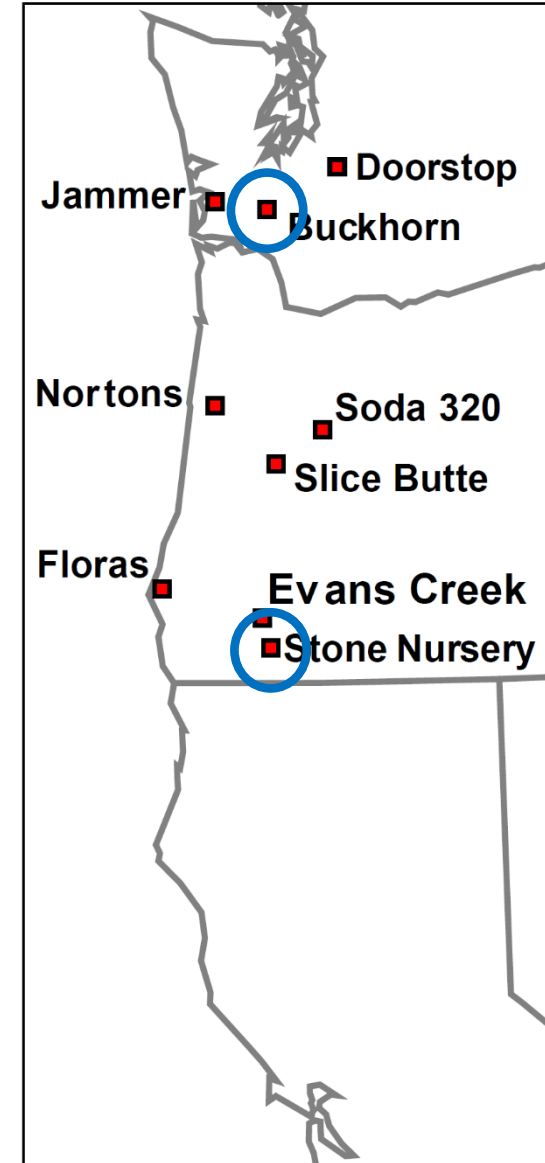

Douglas-Fir Seed Source Movement Trial

- Established 2009
- 60 populations from different regions
- 9 planting locations in diverse environments

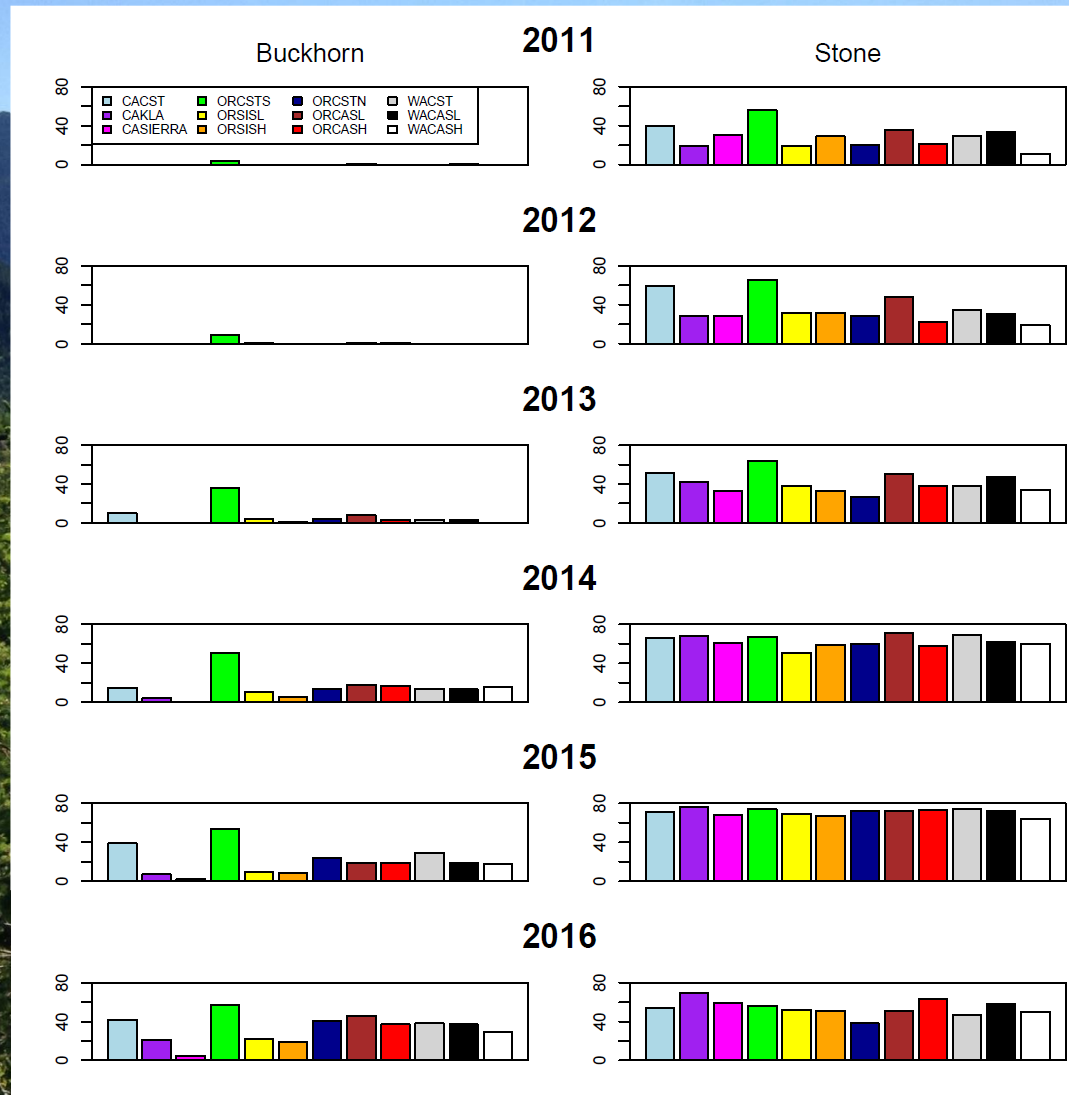

Populations

Planting Locations

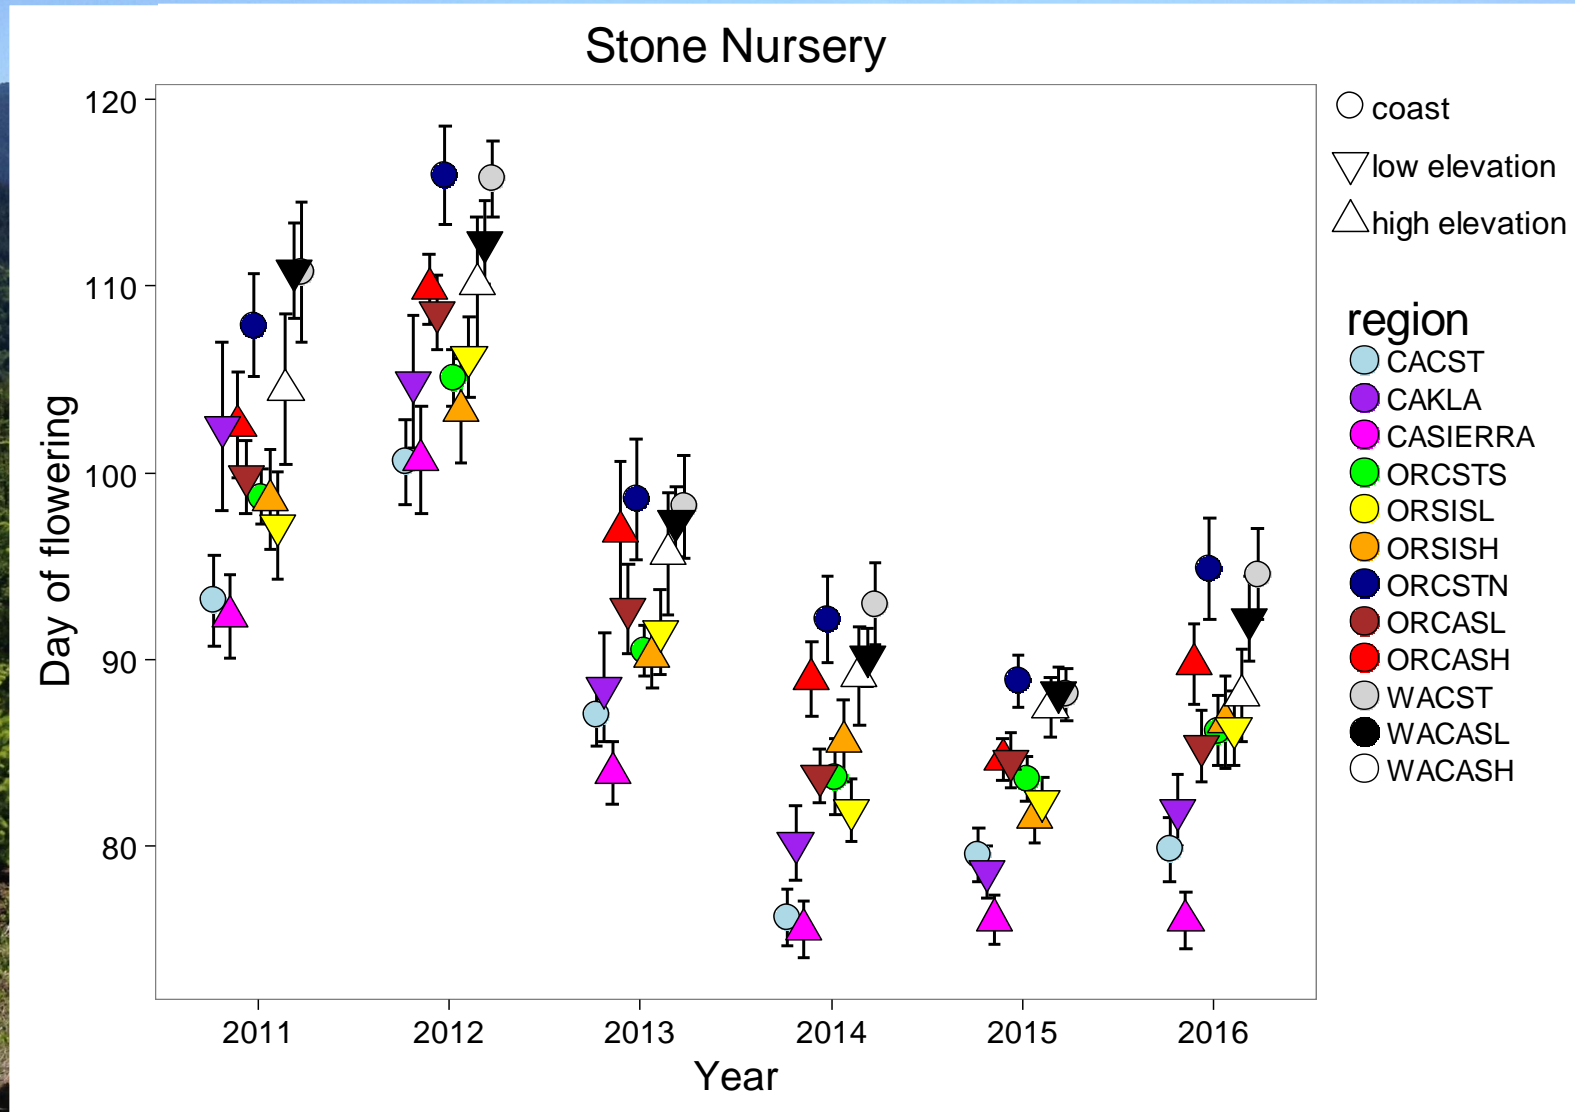

Preliminary results from the Seed Source Movement Trial...

Trees from some regions started flowering **before** others...

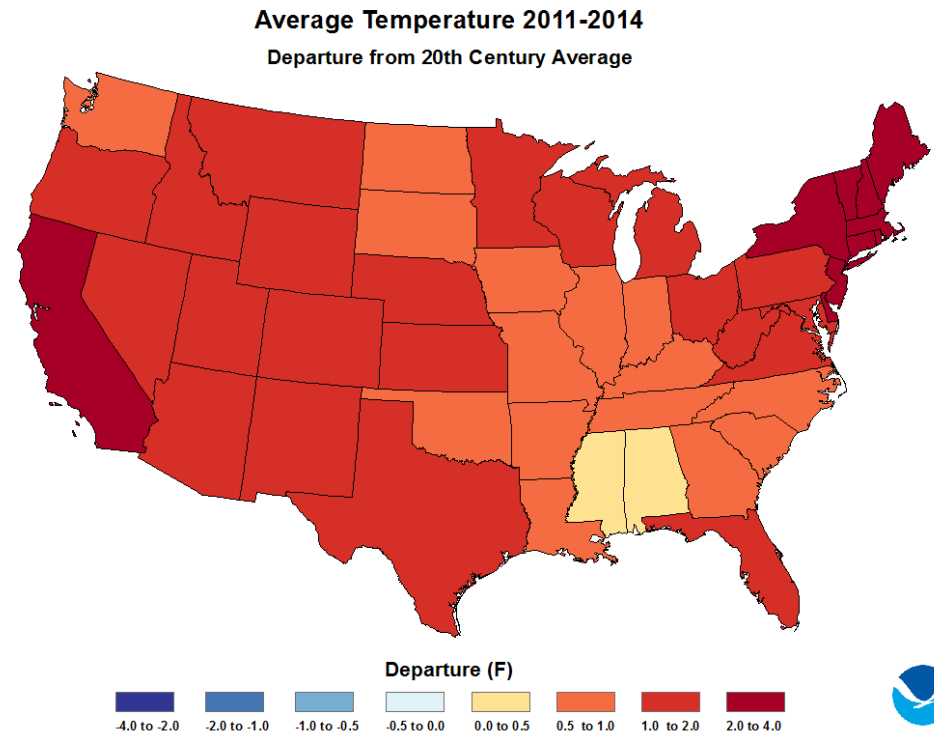

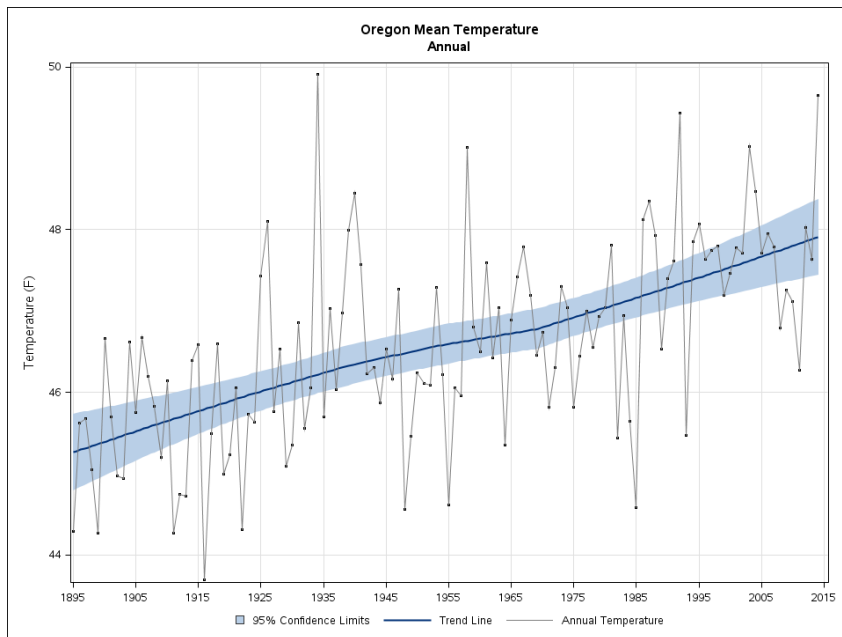

Preliminary results from the Seed Source Movement Trial...

Trees from some regions **flower earlier** in the year.

Importance

- Climate change will affect when trees flower, and this will **influence the success** of pollination and seed development
- Understanding the **environmental cues** that determine timing of flowering will help us predict changes, and manage for more desirable/adaptable trees in the future

Want to help?

- Breeding, crossing, or pollen collection data for either Douglas-fir or Western red-cedar
- We are especially interested in **multiple years of data** on trees from different seed sources
- Local climate data (daily temperature and precipitation data)
- All data is **confidential**, we will not share genetic identity information with anyone!

Hobo weather station at a Seed Source Movement Trail site

Want to help?

If you are willing to share data or have any questions, contact Janet:

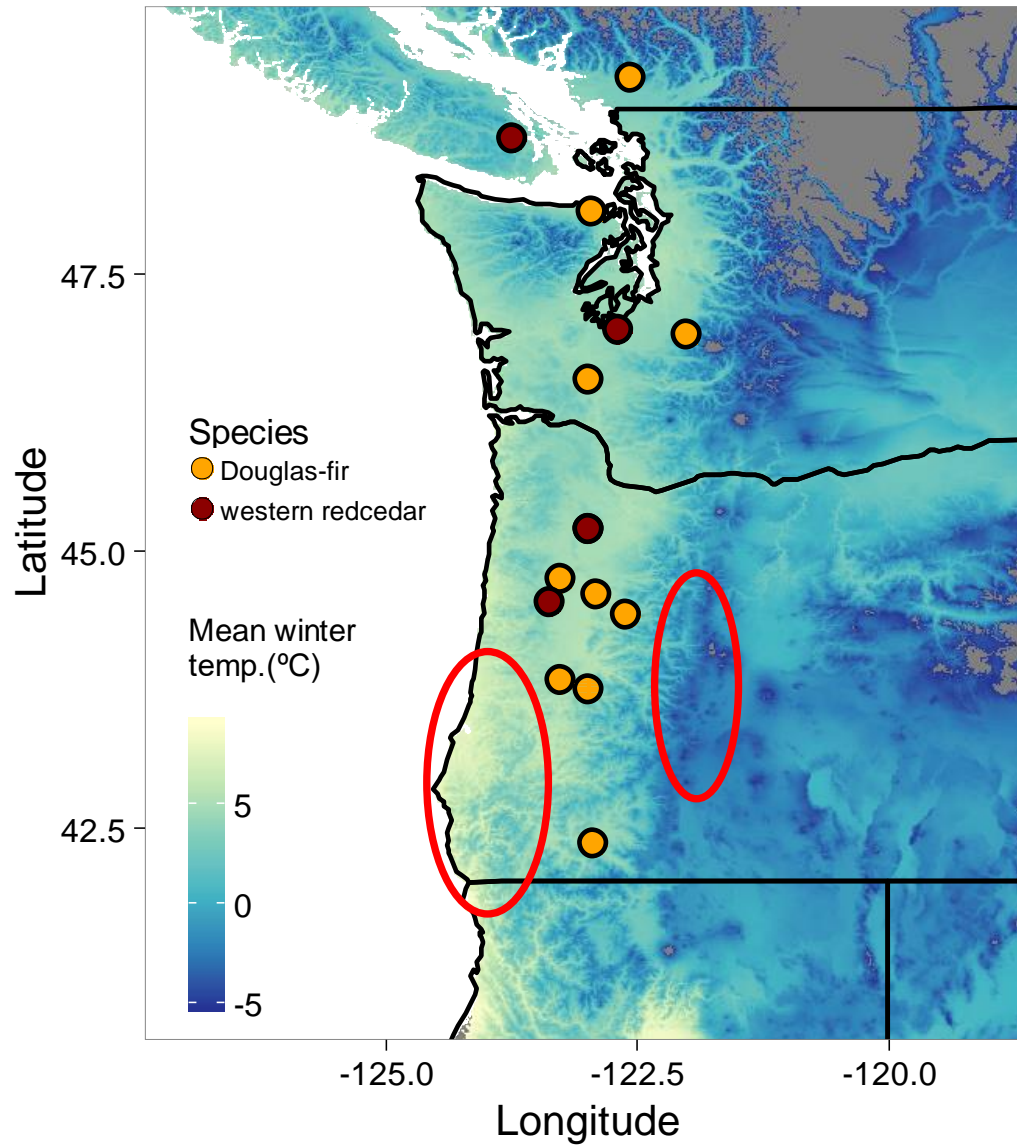

jprevey@fs.fed.us

- Electronic **OR** paper data
- Should have minimal impact on you
- We could enter data and share back with **you**

Hobo weather station at a Seed Source Movement Trail site

We would also like data from orchards with different climates!

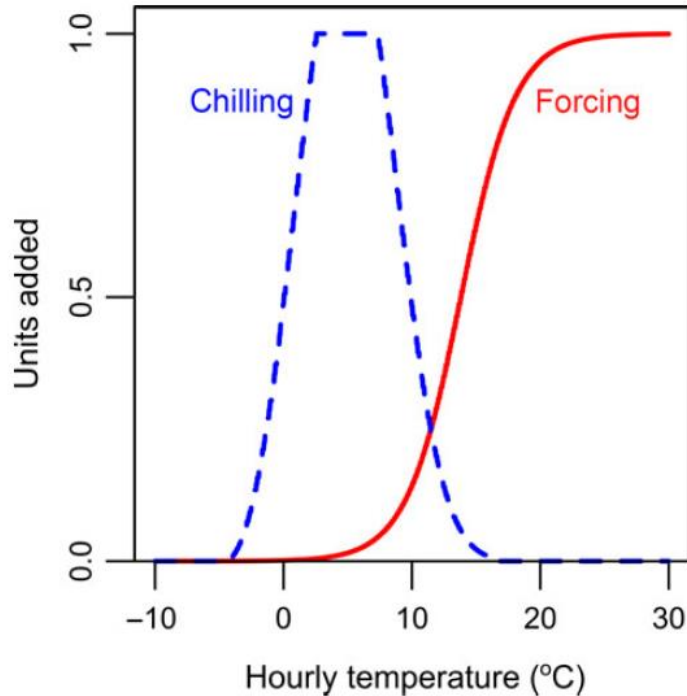

Thank you!

Janet Prev y
jprevey@fs.fed.us

Chilling and forcing models

$$CU = 3.13 \left(\frac{T + 4.66}{10.93} \right)^{2.10} e^{-(T+4.66/10.93)^{3.10}}$$

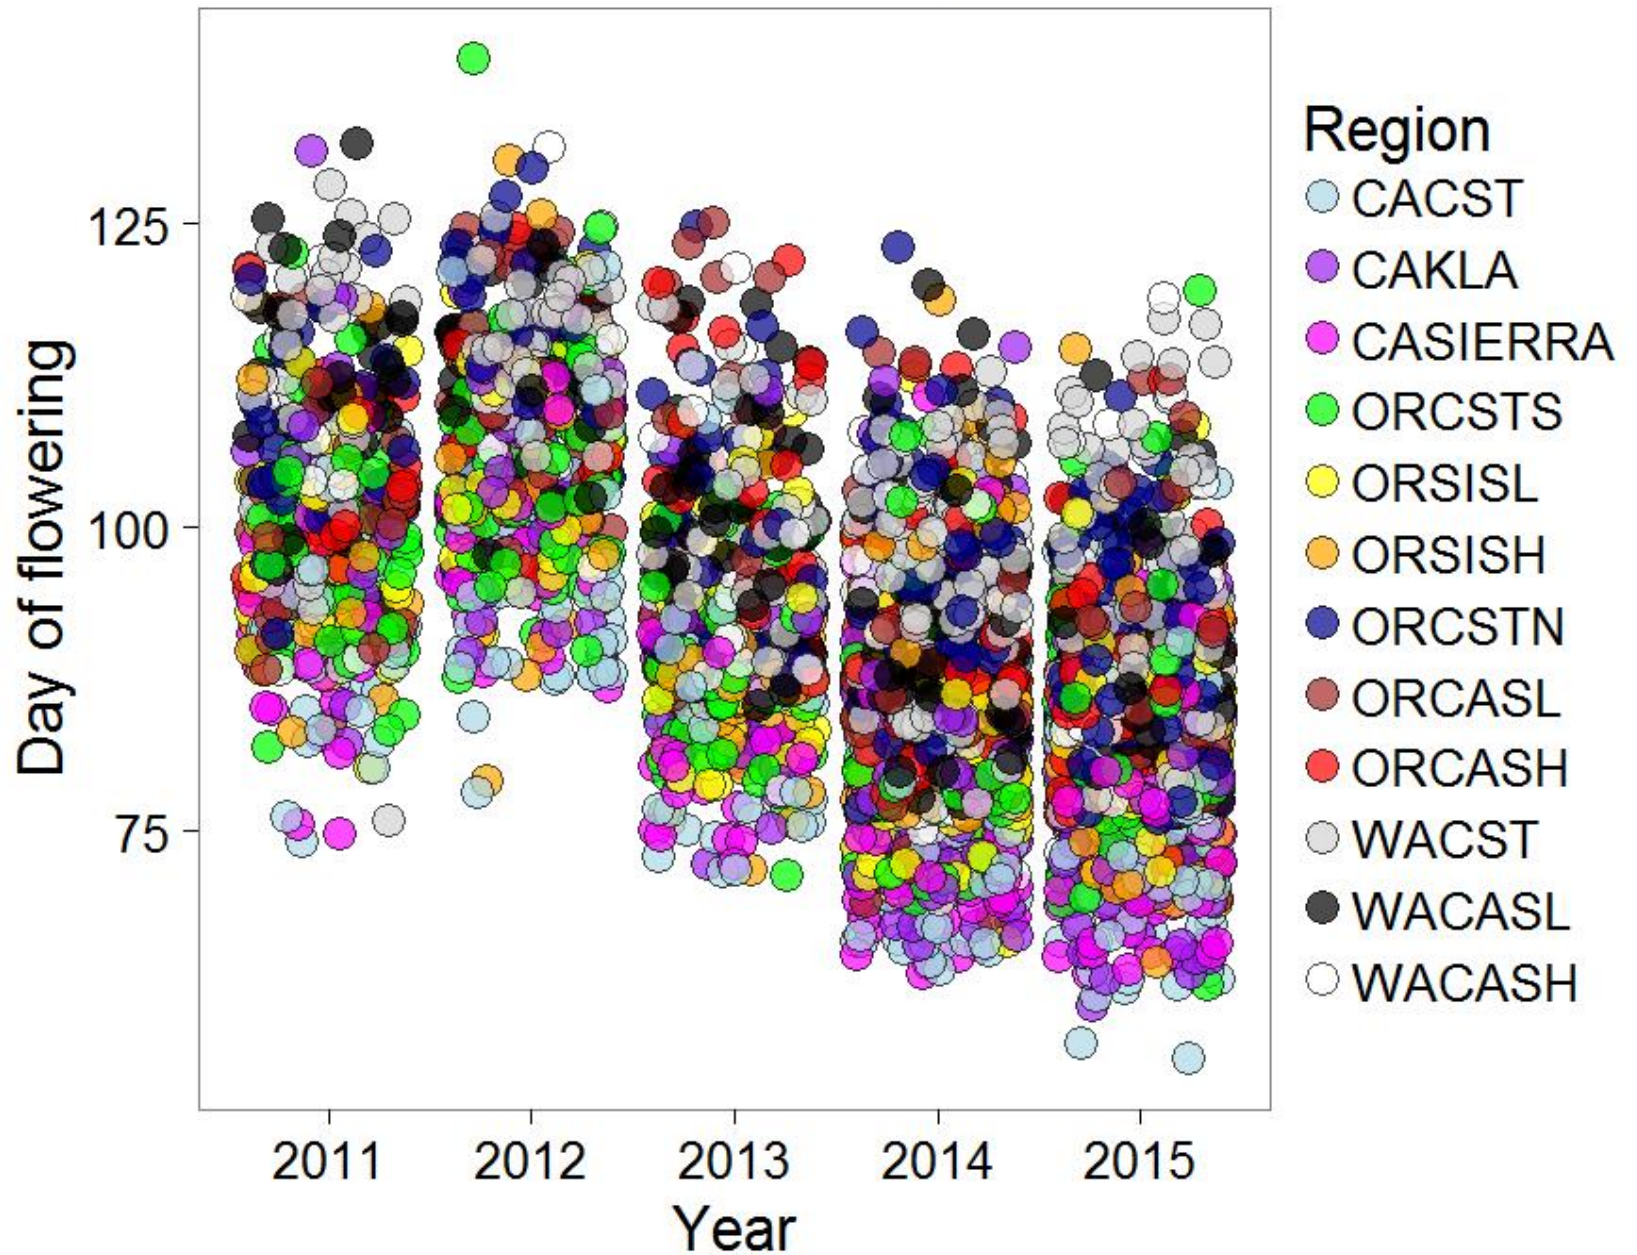

$$FU = \frac{1}{1 + e^{-0.47T+6.49}}$$

Fig. 2 The functions that depict how trees sense chilling and forcing (i.e., accumulate chilling/forcing units), based on hourly temperature from November 1 through growth initiation. See Harrington *et al.* (2010) for a description of function development.
