

Applications of UAV in forest monitoring: a regeneration survey case and an ice damage case

Bogdan Strimbu

Forest Monitoring

IUFRO: “the regular and periodic measurement of certain parameters of forests (physical, chemical, and biological)”

- Specifics:
 - Constant
 - Multiple objective

Constant & multi-objective measurements

- Key factor → Procedure

Field vs. Remote Sensing

- Field: Slow & Sample

 Accurate
- Remote Sensing: Fast & Population

 Relatively accurate

Winning Team

1. Unmanned Aerial Vehicles

2. Sensors

3. Computer Vision / Machine Learning

UAV

- Combination of two worlds: Remote Sensing & Field

- Requires field visit
- Provide population estimates

- High accuracy at affordable prices
- Best case: forester with RS expertise

Sensors

Machine Learning

- Algorithms for processing
 - Large amount of data
 - Low quality data

Objective

- Reduce costs in forest monitoring
- Timely intervention
- Assess damage or success

Regeneration survey

- Western Oregon

Regeneration survey

- Western Oregon

Detail

Only Remote Sensing

Results

- 2 people (could be only one)
- Remote Sensing not the perfect solution
 - Lack of appropriate sensor (IR)
- Human intervention - crucial for accuracy
- <math><1/2</math> day the entire process

Ice Damages

- Western Oregon
- Winter 2015

Ice Damage (2)

Ice Damage (3)

UAV – RGB - Machine Learning

UAV-RBG-Machine Learning

Broken tops and fallen trees

Results

- 2 people (could be only one)
- <1/2 day work
- \$1500 equipment
- Remote Sensing → Accuracy > 95%
- **Why? High resolution RGB orthophoto ~ 1 inch**

Conclusion

- UAV useful tool
 - Price
 - Quality
- Remote sensing
 - Accurate
 - Fast
 - Other attributes – growth, health, composition, etc
- Snapshot of history
