#### Introduction

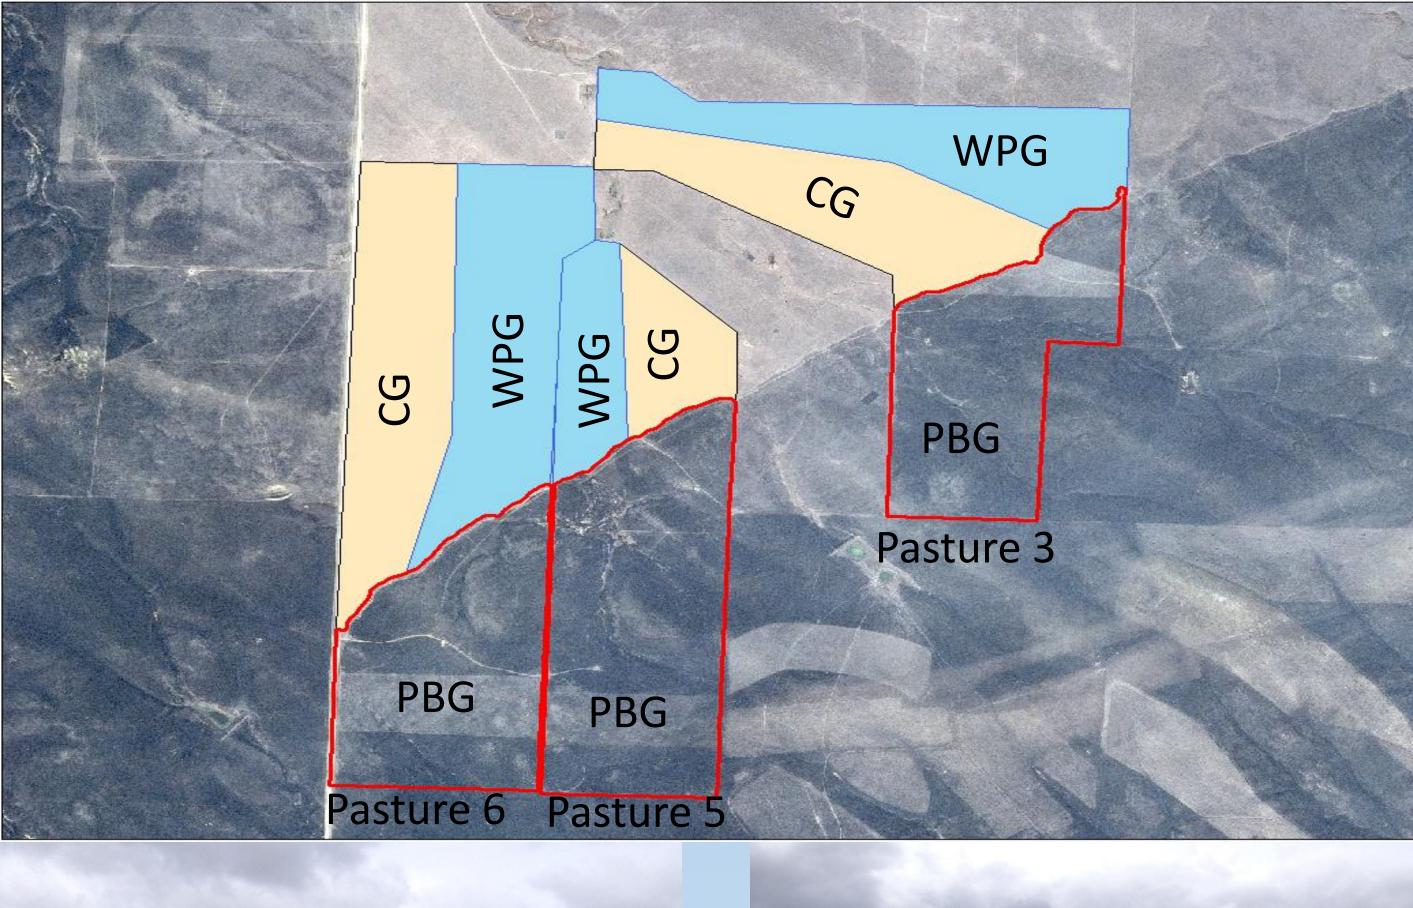

- Northern Great Plains evolved under grazing and fire.
- Creates mosaic of plant communities and structure
- Patch burn grazing (PBG) is effective in increasing heterogeneity on the landscape.
- Many landowners are averse to fire due to concerns of property and forage loss.
- Intensive Winter-Patch Grazing (WPG) is being studied as an alternative non-pyric management strategy for creating heterogeneity.

### Objective

Compare effects of a wildfire burned patch (PBG), a WPG patch, and an untreated control patch (CG) on vegetation structure and livestock use patterns.

### Site Description

- Cottonwood Research Station, South Dakota
- Northern mixed-grass prairie
- Wildfire burned portion (PBG) of each pasture Fall 2016
- Other portions of pastures heavily grazed (WPG) in fallwinter 2016 - 2017.
  - Patch intensively grazed by cows to reduce standing dead forage and vegetation structure.

#### Methods

- Pleiades satellite tasked to image site in May 2017
  - NDVI used to compare "greenness" of treatments
- Live and standing dead vegetation height transects recorded in spring 2017.
- Pastures grazed by yearling steers May-July 2017
  - Subset fitted with GPS collars to track movement
  - Preference Index (PI) calculated for each treatment
  - $PI = \frac{\% \text{ of GPS points in treatment}}{\% \text{ of pasture treatment occupies}}$
  - Data Analyzed in Program R using ANOVA for pasture X treatment effects

#### Results

Table 1: Treatment effect on spring standing dead and current year growth height. A significant pasture x treatment effect (P<0.001) was observed.

Pasture	Treatment	Mean Standing Dead Height	Mean Current Growth Height
3	CG	21.6 <sup>B</sup>	22.6 <sup>B</sup>
3	WPG	9.6 <sup>D</sup>	17.5 <sup>C</sup>
3	PBG	O <sup>F</sup>	13.7 <sup>DE</sup>
5	CG	24.7 <sup>A</sup>	26.0 <sup>A</sup>
5	WPG	7.9 <sup>D</sup>	13.4 <sup>DE</sup>
5	PBG	O <sup>F</sup>	12.0 <sup>E</sup>
6	CG	16.8 <sup>C</sup>	23.5 <sup>AB</sup>
6	WPG	4.9 <sup>E</sup>	16.3 <sup>CD</sup>
6	PBG	O <sup>F</sup>	11.8 <sup>E</sup>

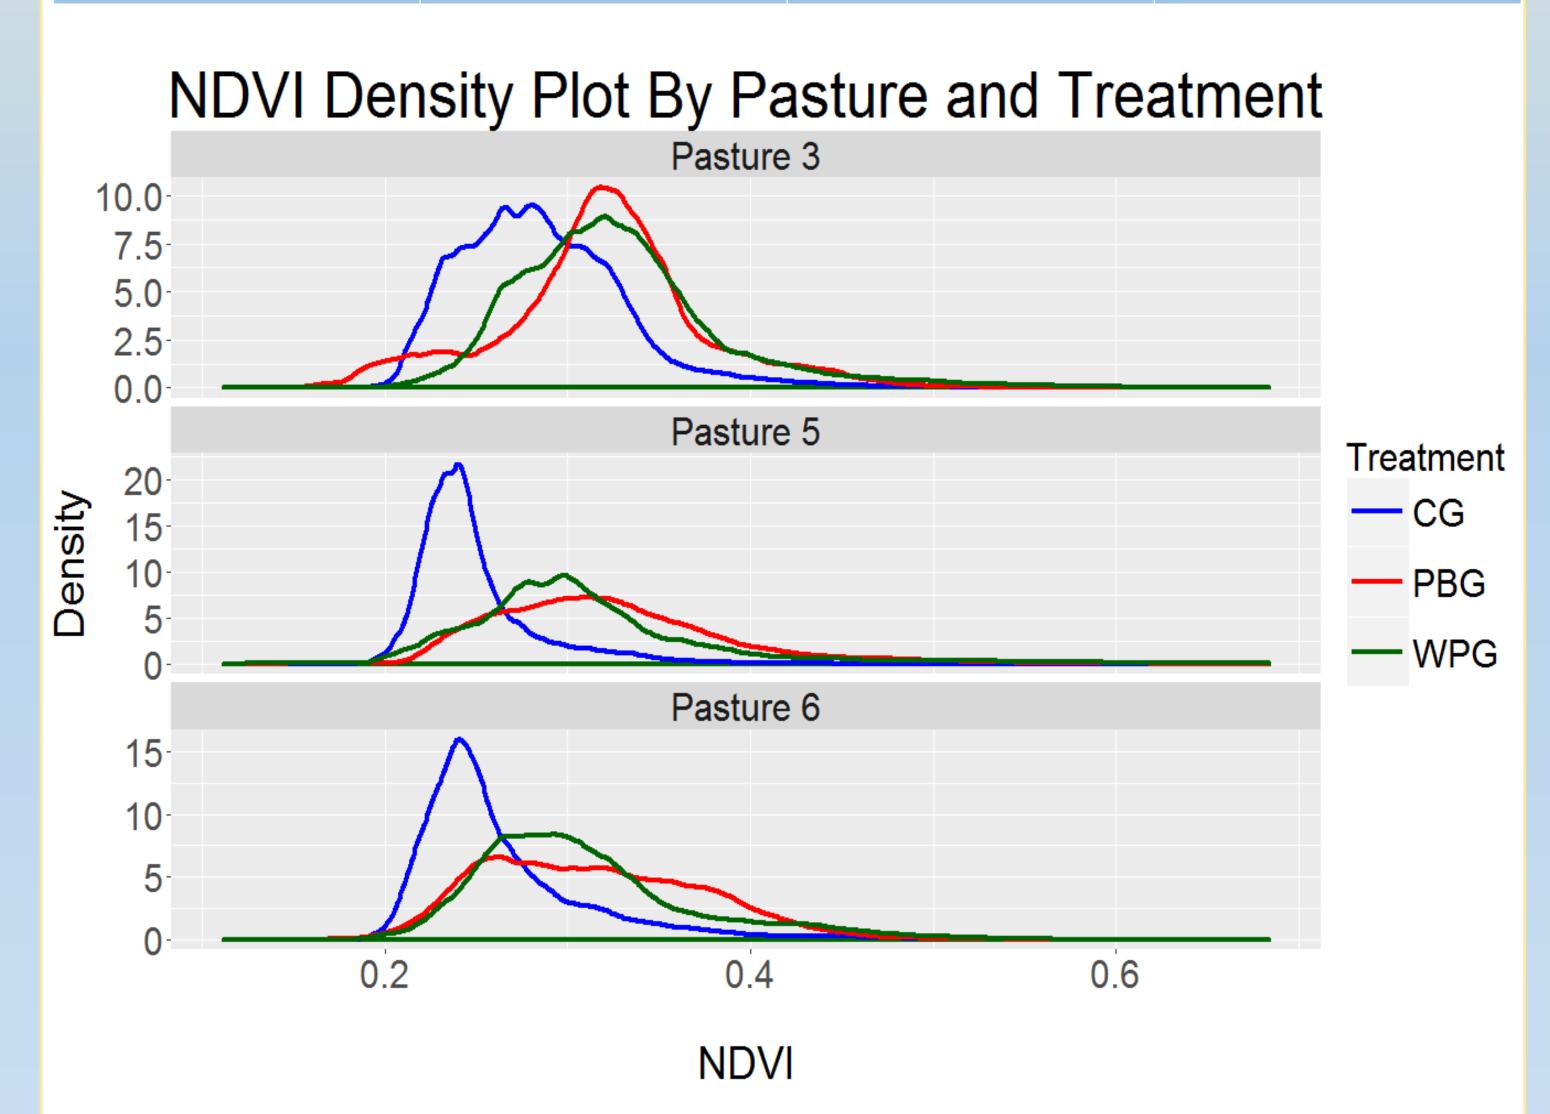

Figure 1: Density plot of NDVI values for each treatment and pasture. Higher NDVI value indicates "greener" vegetation.

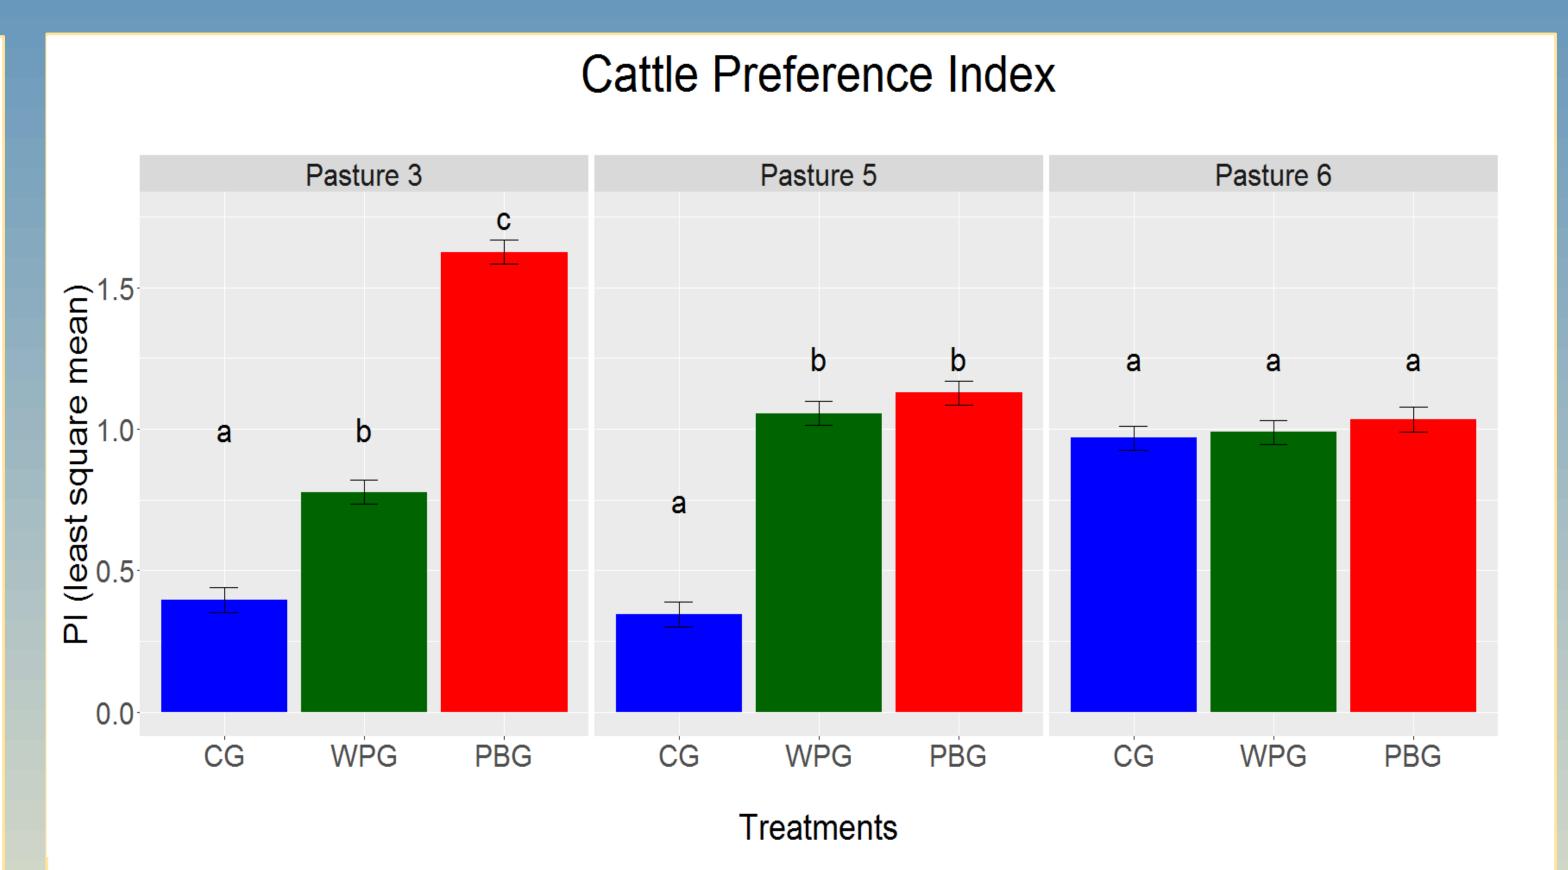

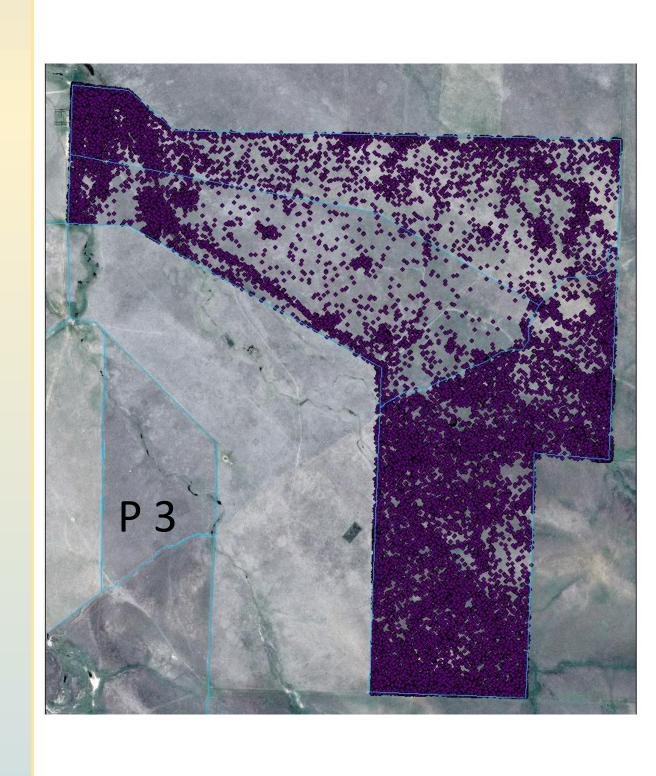

Figure 2: Preference index values for livestock use for each treatment and pasture. A significant pasture x treatment effect was observed (p < 0.001). Letters indicate significant difference between treatments within pastures.

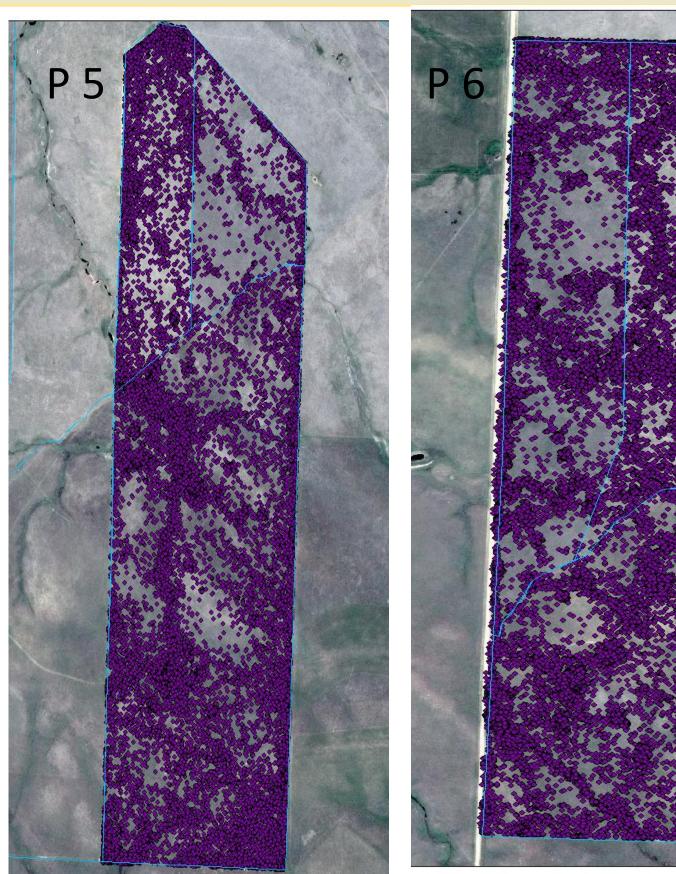

Figure 3: Example of steer GPS locations for each pasture

## Conclusions

- WPG treatment significantly reduced standing dead forage compared to the control.
  - Also resulted in reduction in current year's growth
- Both WPG and PBG treatments resulted higher NDVI values compared to control.
  - Increased "greenness" of pastures likely served as an attractant to grazing livestock
- In all pastures cattle had a higher preference for PBG, followed by WPG then CG.
- WPG is an effective management tool to alter vegetation structure and shift livestock movement on the landscape.
- May serve as a more palatable tool than fire for many land managers.
